CSE 560 Computer Systems Architecture

Instruction Set Architecture

Instruction Set Architecture (ISA)

- · What is an ISA?
 - A functional contract
- All ISAs similar at a high level
 - Design choices in the details
 - 2 "philosophies": CISC/RISC
 - Difference is blurring
- Good ISA...
 - Enables high performance
 - Not a major PITA
- Importance of Compatibility
 - Tricks: binary translation, µISAs

2

ISWhat?

Question: How have I lived such a productive geek life without getting my hands on an ISA?

Likely Answer: Because you are young/started late enough not to have suffered through pre-compiler days.

Snarky Answer: Maybe you weren't as productive as you think you were. ;)

How far are you willing to go for good performance?

Ideally: programmers need only write good programs

In reality: programmers want to see/consider the assembly to improve performance (compiler choices, etc.)

In *some* realities: designers consider ISA alterations to improve performance further

Big Picture (and Review)

4

Program Compilation Machine Code Code Assembly 0x401040 int sum(int x, int y) pushl %ebp movl %esp,%ebp int t = x+v: return t; movl 12(%ebp),%eax addl 8(%ebp),%eax 0×89 0xe5 movl %ebp,%esp 0x8b popl %ebp 0x45

Program written in high-level programming language (C, C++, Java, C#)

- Hierarchical, structured control: loops, functions, conditionals
- Hierarchical, structured data: scalars, arrays, pointers, structures

Assembly language

• Human-readable representation

Machine language

- Machine-readable representation
- 1s and 0s (often displayed in hex)

Code Review

Which of the following statements is false?

- A. A compiler needs to be written with both the programming language and the target ISA in mind.
- B. You can determine the number of static instructions in a program by looking at the assembly code.
- C. A compiler can take assembled code for one ISA and prepare efficient object/machine code for a different ISA.
- D. It's easier to convert assembled code into object/machine code than it is to convert C code into assembly code.
- E. Compiler optimizations usually take place before the assembly code is produced.

- B. You can determine the number of static instructions in a program by looking at the assembly code.
- C. A compiler can take assembled code for one ISA and prepare efficient object/machine code for a different ISA.
- D. It's easier to convert assembled code into object/machine code than it is to convert C code into assembly code.
- E. Compiler optimizations usually take place before the assembly code is produced.

Reasoning About Performance

How long does it take for a program to execute?

Three factors

- 1. How many instructions must execute to complete program
- 2. How fast is a single cycle
- 3. How many cycles does each instruction take to execute

8

Maximizing Performance

Execution Time =

instructions program cycle

cycles instruction

Instructions per program:

- Determined by program, compiler, instruction set architecture (ISA) Seconds per cycle: clock period
- Typical range today: 2ns to 0.25ns
- Reciprocal is frequency: 0.5 GHz to 4 GHz (1 Hz = 1 cycle per sec)
- Determined by micro-architecture, technology parameters

Cycles per Instruction: CPI

- Typical range today: 2 to 0.5
- Determined by program, compiler, ISA, micro-architecture

Minimum execution time \rightarrow minimize each term

• Difficult: often pull against one another

What is an ISA?

10

What Is An ISA?

ISA (instruction set architecture)

- · A well-defined hardware/software interface
- The "contract" between software and hardware
 - Functional definition of operations, modes, and storage locations supported by hardware
 - Precise description of how to invoke, access them
- Included in ISA:
 - Actual machine instructions (instruction set)
 - Storage interface (registers and memory)
 - Operating modes (user mode vs. supervisor mode)

What Is Not In The ISA?

- Not in the "contract": non-functional aspects
 - How operations are implemented
 - Which operations are fast, which are slow and when
 - Which operations take more/less power
 - · How memory is implemented
 - Whether or not there is a cache
- · Gardener Example

ISA as Contract (1)

Which of the following is considered part of an ISA?

- A. Whether a multiply can operate on data still in memory.
- B. Whether branch prediction is used.
- C. The number of cycles it takes to execute a multiply.
- D. The number of physical registers the machine has.
- E. Whether instructions can be executed out of order.

ISA as Contract (1)

ISA Design Goals

What Makes a Good ISA?

- 1. Programmability
 - Easy to express programs efficiently?
- 2. Implementability
 - Easy to design high-performance implementations?
 - More recently: low-power, high-reliability, low-cost
- 3. Compatibility
 - · Easy to maintain programmability as languages and programs evolve?
 - x86 (IA32) generations: 8086, 286, 386, 486, Pentium, PentiumII, PentiumIII, Pentium4, Core2...

1. Programmability

- Easy to express programs efficiently? For whom?
- Before 1985: human
 - Compilers were terrible, often code hand-assembled
 - Want high-level coarse-grain instructions
 - As similar to high-level language as possible
- After 1985: compiler
 - Optimizing compilers generate better code than we do
 - Want low-level fine-grain instructions
 - Compiler can't tell if two high-level idioms match exactly

Human Programmability

- What makes an ISA easy for a human to program in?
 - · Proximity to a high-level language (HLL)
 - Closing the "semantic gap"
 - Semantically heavy (CISC-like) insns that capture complete idioms
 - "Access array element", "loop", "procedure call"
 - Example: SPARC save/restore

 - Bad example: x86 rep movsb (copy string)
 Ridiculous example: VAX insque (insert-into-queue)
 - "Semantic clash": what if you have many high-level languages?
- Stranger than fiction
 - People once thought computers would execute language directly
 - Fortunately, never materialized (but keeps coming back around)

Today's Semantic Gap

- Today's ISAs are actually targeted to one language...
- ...Just so happens that this language is very low level
 - · The C programming language
- Will ISAs be different when Java/C# become dominant?
 - Object-oriented? Probably not
 - Support for garbage collection? Maybe
 - Support for bounds-checking? Maybe
 - Whv?
 - Smart compilers transform HLL to simple instructions
 - · Any benefit of tailored ISA is likely small

19

Compiler Optimizations (1)

Compilers do two things

- Code generation
 - Translate HLL to machine insns, 1 statement at a time
- Optimization
 - Preserve meaning but improve performance
 - Active research area, but some standard optimizations
 - Register allocation, common sub-expression elimination, loop-invariant code motion, loop unrolling, function inlining, code scheduling (to increase insn-level parallelism), etc.

20

Compiler Optimizations (2)

- · Reduce dynamic insn count primarily
 - Redundant computation, more things in registers
 - + Registers are faster, fewer loads/stores
 - ISA can make this difficult by having too few registers
- · Also reduce:
 - · Branches and jumps
 - · Cache misses
 - Dependences between nearby insns (for parallelism)
 - ISA can make this difficult by having implicit dependences
- How effective are these?
 - + Can give 4X performance over unoptimized code
 - Collective wisdom of 40 years ("Proebsting's Law": Compiler Advances Double Computing Power Every 18 Years)
 - Funny but ... don't laugh at 4X performance

21

ISA as Contract (2)

Which of the following is not considered part of an ISA?

- A. The number of architected registers a machine has.
- B. Whether the compiler can inject prefetch instructions.
- C. Whether the machine has a vector unit.
- D. Whether a data is stored in the cache after it is fetched from memory.
- E. The number of bits it takes to encode each instruction.

22

ISA as Contract (2)

Which of the following is not considered part of an ISA?

- A. The number of architected registers a machine has.
- B. Whether the compiler can inject prefetch instructions.
- C. Whether the machine has a vector unit.
- D. Whether a data is stored in the cache after it is fetched from memory.
- E. The number of bits it takes to encode each instruction.

2. Implementability

- Every ISA can be implemented
 - Not every ISA can be implemented efficiently
- Classic high-performance implementation techniques
 - Pipelining, parallel execution, out-of-order execution
- · Certain ISA features make these difficult
 - Variable instruction lengths/formats: complicate decoding
 - Implicit state: complicates dynamic scheduling
 - Variable latencies: complicates scheduling
 - Difficult to interrupt instructions: complicate many things
 - Example: memory copy instruction

2

3. Compatibility

- In many domains, ISA must remain compatible
 - IBM's 360/370 (the first "ISA family")
 - Another example: Intel's x86 and Microsoft Windows
 - x86 one of the worst designed ISAs EVER, but survives
- · Backward compatibility
 - New processors supporting old programs
 - Can't drop features (cumbersome)
 - Or, update software/OS to emulate dropped features (slow)
- Forward (upward) compatibility
 - Old processors supporting new programs
 - Include a "CPU ID" so the software can test of features
 - Add ISA hints by overloading no-ops (example: x86's PAUSE)
 - New firmware/software on old processors to emulate new insn

The Compatibility Trap

- Easy compatibility requires forethought
 - Temptation: some ISA extension gives 5% perf. gain
 - $\bullet\,$ Often: gain diminishes, disappears, or turns to loss
 - Must continue to support gadget for eternity
 - Example: register windows (SPARC) makes OoO difficult
- · Compatibility trap door
 - How to rid yourself of some ISA mistake in the past?
 - Make old insns an "illegal" insn on new machine
 - OS handles exception, emulates instruction, returns

• Slow unless extremely uncommon
